Abstract

A compact, light-weight, stainless-steel injector unit has been developed which operates on liquefied petroleum gas. The use of liquefied petroleum gas eliminates the necessity for an air compressor while the use of stainless-steel greatly reduces the corrosion which otherwise results when acetic acid is used in the bubblers.

The stainless-steel propane Injector

Introduction

Compressed-air operated aspirators have been used at a number of experimental stations for aspirating air through the bubblers used in estimating the concentration of C. & G. agents in the atmosphere. For the aspirators to operate over a reasonably long period at a flow rate of 5-20 liters per minute, either an inconveniently large low-pressure tank or a smaller high-pressure tank is required. Small high-pressure tanks are customarily used, which require a multi-stage compressor. For field use this arrangement is cumbersome and apt to require considerable attention. Furthermore, the use of brass or bronze aspirators with bubblers filled with 50% acetic acid has caused troublesome corrosion especially in the jet.

In the development of the Becken H-recorder, a small stainless-steel aspirator was designed which operated on liquefied petroleum gas. This development suggested the possible use of liquefied propane or butane for drawing air samples through the bubblers used in field experiments, which would eliminate the necessity for the air compressor and reduce corrosion problems. A suitable aspirator for this purpose is described in this report.

Experimental

The aspirator unit is an adaptation of the Norton injector which has been in use for some time by British and Canadian investigators. To determine the optimum jet and throat diameters, three different jets and three different throats were made up, after studying a report on the British injector. The nine combinations were tested experimentally, using a propane-butane mixture. The combination which gave the

RESTRICTED

RESTRICTED

2.

maximum efficiency through a Porton lead-filled bubbler containing 20 cc. of 50% acetic acid was selected for production.

A flow-rate of 5-20 liters per minute was originally specified.

Recently there has been a tendency at some stations to use lower flow-rates. Although the aspirator will perform satisfactorily at flow-rates under 5 liters per minute, its efficiency under load is not as great as it is in the range for which the aspirator was originally designed.

A cross-section of the aspirator is shown in Figure 1, and the complete unit is shown in Figure 2. The unit includes the aspirator, a pressure regulator, a gas filter, a 0-30 p.s.i. gauge to indicate the jet pressure and a 0-250 p.s.i. gauge to indicate the pressure in the supply tank.

Performance

The following performance tests were carried out using a commercial, liquefied petroleum gas having an apparent molecular weight of 50. This corresponds roughly to a mixture 50% by weight propane and 50% butane. The composition changes during use, of course, becoming richer in butane.

Fuel Consumption. The fuel consumption varies with the jet pressure employed and is shown graphically in Figure 3. The fuel consumption is given both in terms of pounds (avoirdupois) of fuel per hour and in terms of liters of gas (S.T.P.) per minute.

Suction Developed. The suction produced with various jet pressures was measured at zero air-flow by connecting a mercury manometer directly to the suction side of the aspirator. The data obtained are shown in Figure 4.

■ RESTRICTED

RESTRICTED

3.

Flow-rates Obtainable. The rate at which air is pumped by the aspirator is a function of both the jet pressure and the load (resistance) in the suction line. The flow through a Norton bubbler filled with glass beads and containing 20 cc. of 50% acetic acid is shown as a function of jet pressure in Figure 5.

After the aspirators had been completed, their possible use in connection with the Cascode impactor was suggested. Since no impactor was available for test, one was simulated by means of an adjustable valve in the suction line using the data on the impactor furnished by Capt. Heeser of the C.A.S. The valve was set so that the pressure drop across it was the same at each flow-rate as in the impactor. One setting actually gave a load which had characteristics closely conforming to the real impactor. With this simulated impactor in the suction line, flow-rates were measured as a function of jet pressure. The results are shown in Figure 6.

The Efficiency of the Aspirator. The efficiency of the aspirator varies with the load and the flow-rate used. The efficiency, expressed as the gas-flow (both at the same conditions of pressure and temperature), is plotted as a function of jet pressure in Figure 7. Curve A shows the efficiency through the Norton bubbler and Curve B gives efficiency data when used with the simulated Cascode impactor.

Size of Fuel Tank Required. In estimating the size of fuel tank required, special attention must be given to the flow-rates, to the composition of the liquid fuel and to the temperature to which the tank

RESTRICTED

RESTRICTED

4.

will be subjected. At higher flow-rates a larger tank is needed, not only because the fuel is consumed more rapidly but also because of the greater refrigerating effect and the accompanying drop in gauge pressure. To insure good pressure regulation, the gauge pressure should not be permitted to drop below a value twice the jet pressure employed. For jet pressures under 6 p.s.i.c., a tank holding 10 lbs of the liquid fuel should be large enough but a 25 lb. (or larger) tank is recommended if higher jet pressures are required.
